

SYSTEM ID: Modena

NARRATIVE DESCRIPTION

The Modena system is a simplified version of the water distribution system in the small town of Modena, Italy. The system has an average demand of 53,000 CMD. The network was first presented by Bragalli et al. (2008) as part of a design study. A general schematic of the system is shown below. The system has four reservoirs and 72 kilometers of pipe.

NETWORK SCHEMATIC:

HISTORY OF THE NETWORK FILE

The Modena system was originally developed by Bragalli et al. (2011) using mixed integer nonlinear programming. Since then, it was optimized in various studies using the multi-objective hybrid approach (Creach & Fanchini, 2014) and by incorporating domain knowledge into a genetic algorithm model (Bi et al., 2014).

ABSTRACT: A new computer model called Genetic Algorithm Pipe Network Optimization Model (GENOME) has been developed with the aim of optimizing the design of new looped irrigation water distribution networks. The model is based on a genetic algorithm method, although relevant modifications and improvements have been implemented to adapt the model to this specific problem. It makes use of the robust network solver EPANET. The model has been tested and validated by applying it to the least cost optimization of several benchmark networks reported in the literature. The results obtained with GENOME have been compared with those found in previous works, obtaining the same results as the best published in the literature to date. Once the model was validated, the optimization of a real complex irrigation network was carried out to evaluate the potential of the genetic algorithm for the optimal design of large-scale networks. Although satisfactory results have been obtained, some adjustments would be desirable to improve the performance of genetic algorithms when the complexity of the network requires it.

SYSTEM CLASSIFICATION:

PIPE/LOOP HISTOGRAM:

Hoagland et al. (2015) designed a network classification algorithm for use in classifying water distribution systems as either “branched,” “looped,” or “gridded” based on the observed frequency of network loops with different numbers of distinct pipe segments. The frequency distribution for the Pescara system is provided below. Using this information, Hoagland et al., classified this system as being a LOOPED system.

# Total Pipes:	317
# Branch Pipes:	4
Ratio (Branch Pipes / Total Pipes):	0.01

Figure 3.4. Classification Algorithm (Hoagland et al., 2015)

NETWORK STRUCTURE METRICS:

Building on the work of Hoagland et al., (2015), Hwang & Lansey (2017) created an expanded classification system that allows for further classification of a system as being either a transmission or distribution branched, looped, gridded, or hybrid system. Their algorithm streamlines the classification system by removing unnecessary nodes that do not contribute to the structure of the system while still retaining their use as intermediate points for demand data entry. A full description of the algorithm can be found in the cited reference.

Application of the Hwang and Lansey classification algorithm to the system yields the following statics and associated classification:

Parameter	Value
Edges	317
Pipes	317
Nodes	272
Average Diameter	127
Reduced Nodes	72
Reduced Edges	117
Branched Edges	4
Branched Index	0.0
Meshed Connectedness	0.1
Reduced Meshed Connectedness	0.33
Link Density	0
Average Node Degree	2.3
Hwang & Lansey Classification	Distribution Dense-Grid
